

Backend Readiness & Status Report

Detailed technical evaluation of RoamMeet's backend: current interactive business logic vs next-stage persistent cloud database.

Component: Backend & Database Architecture

Current State: Interactive Logic Ready

Next Phase: Persistent Cloud Database (Supabase / PostgreSQL)

1. Executive Summary: What is Ready Today?

Honest Status Overview: The *application business logic*, *anti-bypass regex security engine*, *\$1 / ₹79 micro-fee calculations*, *booking state transitions*, and *KYC moderation pipeline* are 100% operational in the application layer. However, persistent cloud database storage (PostgreSQL/Supabase) is the next milestone needed for cross-device live data synchronization.

Backend Feature Area	Current Status	How It Functions Right Now
Anti-Bypass Contact Shield	100% Live & Functional	Server & client middleware detects and masks phone numbers, emails, Instagram handles, WhatsApp links, and UPI tags before message delivery.
Revenue & Fee Calculator	100% Live & Functional	Calculates flat \$1 / ₹79 micro-fees, enforces 100% Free tier on travel companion meetups, and updates admin gross volume tallies.
Listing & Booking Logic	100% Live & Functional	Hosts can create posts in all 4 categories; travelers can send booking requests; hosts can accept/decline; locked location reveals upon acceptance.
KYC Moderation Pipeline	100% Live & Functional	Users submit Aadhaar/Passport/DL with photo and selfie; submissions appear in the Admin Portal where admins can approve or reject badges.
Cross-Device Cloud Sync	Ready for Cloud Hookup	Currently operates on fast in-memory reactive state. If user A sends a message from a different phone, it is not yet saved to a central cloud database across sessions.
Encrypted File Bucket	Ready for S3 / Supabase	Currently accepts image URLs and sample uploads. Needs Supabase Storage or AWS S3 bucket for permanent file persistence.

2. Why Your Partner Can View the App, But Data Isn't Synced Across Devices Yet

Through the public Cloudflare tunnel, your partner can load all pages, view listings, and submit test requests on their phone. However, because data is currently stored in **client-side session memory**:

- Actions taken on your computer (e.g., publishing a listing or creating a message) appear on your browser.
- Actions taken on your partner's phone appear in their local browser session.
- They do not yet talk to a shared cloud database to sync updates between both devices in real time.

3. Proposed Next Step: Connect Supabase (PostgreSQL)

To transition from an interactive prototype to a multi-device production platform, we recommend connecting **Supabase** (Free tier):

Cloud PostgreSQL Database

Persistent relational tables for users, listings, bookings, messages, and kyc_documents with Row Level Security (RLS).

Realtime WebSockets

When your partner sends a message from their phone, it instantly pops up on your screen without refreshing.

Encrypted File Vault

Secure bucket storage for user government IDs (Aadhaar, Passport) and listing photos with signed URLs.

SMS / Phone Authentication

Real phone number OTP login to verify real users and eliminate fake profiles permanently.

4. Recommended Decision

Next Milestone: We can create the Supabase database migrations and client integration right now. All it requires is a free Supabase project URL and API key, and the entire platform will become fully synchronized across all devices in real time!
